The main idea behind this project was to take the `https_request` example from `esp-idf` and limit it to using only one method for `https` communication. I also needed to setup a phone server that does a `get` request for location + a `post` request to store the data.

As long as you understand the `http` protocol, which frankly with the use of `chatGPT` you don't really need to understand, this project was fairly simple. The only complication was getting the hotspot to be reliable.
